

DEFINICIÓN

What is PHP?

PHP is an open-source programming language widely used for web development. The name originally stood for *Personal Home Page*, but it now stands for *PHP: Hypertext Preprocessor*. PHP is a server-side language, which means the code is executed on the web server, and the result is sent to the user's browser as HTML.

PHP is popular because it is easy to use, supports various databases (such as MySQL), and integrates well with HTML. It powers millions of websites and platforms, including content management systems like WordPress.

What is CSS?

CSS, or *Cascading Style Sheets*, is a style sheet language used to describe the appearance and formatting of a document written in HTML or XML. While HTML provides the structure of a web page, CSS is used to control the layout, colors, fonts, spacing, and overall visual presentation.

CSS allows developers to separate content from design, making websites easier to maintain and more visually appealing. It also enables responsive design, allowing web pages to adapt to different screen sizes and devices.

EJEMPLIFICACIÓN

Example of PHP

Imagine you have a website where users can submit a contact form. When someone fills out their name, email, and message, PHP can be used to process that information.

For example, a simple PHP script might take the form data, save it to a database, and send an email notification to the website owner.

Example of CSS

For example, imagine you have a simple webpage with a title and a paragraph. By default, everything looks plain. But with CSS, you can style it to make it more visually appealing.
